The WHOQOL-AGE is a combination of the EUROHIS-QOL.8 and the short version of the WHOQOL-OLD. The aim of the present study is to explore the psychometric properties of the Turkish version of the WHOQOL-AGE in terms of its validity and reliability.

Methods: Internal consistency, item–total correlations, and item success were analyzed taking the original structure into account. The validity tests consisted of construct validity and criterion validity analyses. The original scale structure was compared with a proposed new scale structure, comprised of two domains and based on the exploratory and confirmatory factor analysis, in terms of goodness-of-fit measures.

Results: The mean age of the sample population (n = 550) was 73.09 ± 6.77, and 58.9% were female. Skewness and kurtosis were both within accepted limits (<1.0) and the floor and ceiling percentages also showed good measuring capacity (<10%). The Cronbach alpha value was 0.90 for domain 1 and 0.86 for domain 2. The goodness-of-fit analysis results for the original scale structure and the new scale structure, respectively, were comparative fit index = 0.89 and 0.83, Tucker Levis index = 0.87 and 0.81, and root mean square error of approximation (RMSEA) = 0.12 and 0.073.

Conclusion: The WHOQOL-AGE.TR is moderately compatible with the original scale structure. The EFA revealed a new scale structure: the domain 1 (‘satisfaction with physical and mental health and well-being’ domain) includes items 1–5, 9 and 10, and the domain 2 (‘satisfaction with economic and social well-being’ domain) includes items 6–8 and 11–13.

Keywords: Quality of life; Aged; Psychometrics.
INTRODUCTION

Quality of life (QoL) for the elderly is of increasing importance as the frequency of chronic conditions grows worldwide, so health professionals need to implement QoL into their clinic practice for older adults. Therefore, there is a need for age-specific generic QoL scales evaluating quality of life for the older adults (≥65 years of age). The World Health Organization Quality of Life Assessment (WHOQOL) is a tool for the evaluation of QoL in adults, and it has been developed into long (the WHOQOL-100), intermediate (the 26-item WHOQOL-BREF) (1), and short (the 8-item EUROHIS-QOL 8) (2) versions. The WHOQOL group, including the Turkish field center, also developed a supplementary module of the WHOQOL for older adults called WHOQOL-OLD (3), which has widely been used for geriatric and public health research. All of these instruments have been adapted for the Turkish population (4,5). QoL experts recommend using the generic and population/condition-specific QoL instruments to assess QoL in all population groups. The only validated generic QoL instrument for the elderly in Turkey is the 24-item WHOQOL-OLD (3), which has widely been used for geriatric and public health research. All of these instruments have been adapted for the Turkish population (4,5). QoL experts recommend using the generic and population/condition-specific QoL instruments to assess QoL in all population groups. The only validated generic QoL instrument for the elderly in Turkey is the 24-item WHOQOL-OLD. As a result, when using a combination of these QoL tools for elderly patients, a long battery of items has to be applied, which is time-consuming for the professionals and difficult for the older patients to concentrate on. Fang et al. (6) developed three short versions of the WHOQOL-OLD, each consisting of six different WHOQOL-OLD items. The psychometric properties of the Turkish versions of these three short WHOQOL-OLD tools has been presented elsewhere with questionable psychometric results that might be attributed to the item on death and dying (7). Consistent with the Turkish psychometric results, in order to have a brief QoL tool for aging populations, the developers of WHOQOL-AGE dropped the death and dying item and combined the first short version of the WHOQOL-OLD with the EUROHIS-QOL 8 to create a new 13-item QoL instrument for the elderly, WHOQOL-AGE, in a project titled Collaborative Research on Ageing in Europe (COURAGE in Europe) (8). Despite recommendations that both a generic and an age-specific instrument be used for outcomes research, the 24-item WHOQOL-OLD has been frequently used in Turkish studies without combining it with any generic version (WHOQOL-100 or WHOQOL-BREF), mainly to avoid using long instruments in geriatric research. The aim of the present study is to explore the psychometric properties of the Turkish version of the WHOQOL-AGE in terms of its validity and reliability.

MATERIALS AND METHODS

1. Study sample

The study sample consisted of 550 older adults recruited from two districts of Manisa Province to include both an urban and a rural population. The sample size was calculated with 95% confidence, 50% unknown event percentage, and 5% precision. The urban and rural samples were randomly selected from among the urban districts (n=1867) and rural districts (n=1463) of the province by using a multistage sampling method using the records of the district family health centers.

2. Measures

The suggested items of the WHOQOL-AGE were taken from the already translated and validated Turkish versions of the EUROHIS-QOL 8 and the short version of the WHOQOL-OLD. The WHOQOL-OLD short (4) was combined with the EUROHIS-QOL 8 (7). With the item related to death and dying in the short WHOQOL-OLD excluded and a 13-item WHOQOL-AGE-TR was created, as suggested during the development of the original WHOQOL-AGE. So the WHOQOL-AGE 13 item scale structure is composed of EUROHIS-QOL (the first 8 items) and WHOQOL-OLD short items.

All participants completed the Katz Index of Independence in Activities of Daily Living (Katz ADL index) to assess their level of physical independence. The Katz ADL index measures
independence in the six activities of bathing, dressing, toileting, transferring, continence, and feeding. For all six activities together, the possible score range for the Katz ADL index is 0–6 (9). Additionally, all participants answered questions about the presence of any chronic conditions or disabilities and their socio-demographics.

3. Psychometric analyses

The reliability and validity analyses were completed following the descriptive and item distribution analyses.

Both exploratory and confirmatory approaches were employed during the reliability analyses and factor analyses. The exploratory approach was used to probe the possible change in structure of the WHOQOL-AGE, and the confirmatory approach was used to test the predefined and suggested item/domain structure of the original instrument.

3.1 Distributional properties

The distribution properties of each item and predefined domain of the WHOQOL-AGE were determined through skewness and kurtosis analyses, and the measurement capacity of each domain was evaluated through floor and ceiling effects. The limit values were accepted as 1.0 for skewness, 2.0 for kurtosis, and 15% for the floor and ceiling effects (10).

3.2 Reliability analyses

Internal consistency, item–total correlations, and item success (based on the item–domain correlation results) were analyzed with a confirmatory approach by considering the original structure of the WHOQOL-AGE.

Cronbach’s alpha coefficients were calculated to assess the internal consistency of the overall scale and domains of the instrument. The expected minimum satisfactory value for alpha was around 0.7. Alpha values for the case of ‘if item deleted’ were also calculated in order to show the contribution of each item to the scale variances.

For any item that makes a positive contribution to its own domain, the alpha value is expected to be lower than the global alpha value when the – problematic item is removed from the analysis.

Item–total correlations assume that an item should have a correlation coefficient at least 0.3 with the domain it belongs to. The term ‘item success’ refers to the percentage of items that have higher correlations with their domain. In other words, all items are expected to have significantly higher correlation coefficients with the domain they belonged to than with the other domain.

3.3 Validity analyses

The validity analyses consisted of construct validity and criterion validity analyses. Factor, known groups, and convergent validity analyses were employed to examine the construct validity of the scale.

3.3.1 Factor analyses

Both exploratory (EFA) and confirmatory factor analyses (CFA) were done to test the construct validity of the Turkish WHOQOL-AGE-TR. The EFA was run using principal components analyses with oblique (direct oblimin) rotation. Satisfactory fit of the Turkish version to the original WHOQOL-AGE scale structure was tested using several goodness-of-fit indices generated by CFA, such as the comparative fit index (CFI), root mean square error of approximation (RMSEA), and chi-square. The cut-off values of good fit for these indices are >0.90 for CFI, <0.08 for RMSEA, and <2.0 for the ratio of chi-square to degrees of freedom ($\chi^2/df$) (11). The $\chi^2/df$ ratio was preferred since chi-square statistics are sensitive to sample size.

3.3.2 Known groups validity

The known groups validity of the WHOQOL-AGE-TR was tested using the hypotheses that advanced age, poor education, low social class, chronic illness, poor living conditions, inadequate social support, and verbal and/or physical abuse of the elderly can decrease WHOQOL-AGE scores.
3.3.3 Convergent/discriminant validity

The Katz ADL index scores were divided into three categories as ‘totally dependent’, ‘partially dependent’, and ‘independent’, and the mean domain scores of these categories were compared.

3.3.4 Criterion validity

Additionally, a criterion validity analysis was carried out by running a multiple linear regression using the general QoL item of the WHOQOL-AGE (item 1) as a reference dependent variable and the domains as independent variables.

A Students’ t-test was run for the comparison of two independent continuous variables, and a one-way analysis of variance (ANOVA) was used for three or more independent continuous variables, where the parametric test requirements were satisfied and Cohen’s effect size (ES) was used to distinguish the effects of different variables on the WHOQOL-AGE scores (12).

Parametric and non-parametric statistics were used to compare the means where appropriate. Post hoc comparisons were done using the Tukey’s B. Spearman’s correlation was used for the comparison of the two discrete numeric variables. The statistical packages used were SPSS version 23.0 and Lisrel 8.05. The acceptable type 1 error was considered as less than 0.05 in the analyses.

4. Ethical issues

The study was approved by the Ethics committee of Manisa Celal Bayar University (July 10, 2019/Ref 20.478.486).

RESULTS

The mean age of the sample population was 73.09 ± 6.77; 58.9% were female; 31.3% has no education; 22.4% had inadequate income, 29.1% were physically dependent to some extent, 34.0% was living alone; and 77.9% suffered from at least one chronic illness; 21.2% has ever been faced a kind of abuse; 17.2% reported poor relationships with friends or family members.
WHOQOL-AGE-TR are presented in Table 2 according to the original scale structure. The WHOQOL-AGE-TR domain scores and overall scores could be distinguished by all of the subgroups of the known groups variables.

The EFA, run independently using varimax and direct oblimin rotations, revealed a somewhat different domain structure compared to that of the original scale structure proposed by Brown et al. (13) (Table 3). The Kaiser–Meyer–Olkin value was 0.94 (>0.5) and Bartlett’s test of sphericity was significant (p<0.001) for all of the factor analyses. The adjusted coefficient of determination (R2) was 62.5.

In the varimax rotation, even if the unstable items 6,8,10, and 11 were left aside, items 7 and 9 were in unexpected domains in regard to the original structure. In contrast, the direct oblimin rotation stabilized the item loadings of the item 6 and item 8 which were unstable items in the varimax rotation, forming domain 1 consisting of items 1–5,9, and 10 and domain 2 consisting of items 6–8,12, and 13. Only item 11 was found to be unstable in the oblimin rotation. The items 7 and 9 were loaded in unexpected domains, consistently in both Varimax and Oblimin rotation solutions. Eventually, the EFA revealed a two-domain structure in the Turkish version with different item compositions than the original scale structure; domain 1 includes items 1–5,9, and 10, which relate to ‘satisfaction with physical and mental health and well-being’, and domain 2 includes items 6–8 and 11–13, which relate to ‘satisfaction with economic...
and social well-being’. Item 1, the overall QoL item of the WHOQOL-AGE-TR, which is almost equally loaded (unstable) in both domains in the varimax rotation, was decisively included (highly loaded) in domain 1 during the oblimin rotation (Table 3).

The comparison of the EFA results for the rural, urban, and overall data sets by direct oblimin rotation revealed that the rural and urban data sets showed invariance in items 6 and 11 (not shown here due to restricted number tables). Similar invariances for items 12 and 13 were reported from three different country sets in the COURAGE study (14), and these invariances were mainly attributed to socioeconomic variables. In addition to the socioeconomic differences between the rural and urban samples, sociocultural diversity may also contribute to these inconsistencies. For example, item 6, which is related to satisfaction with

*Cohen’s Effect size (18); **Tukey B; ***Original Scale structure; ‡Assessed by Katz index
personal relationships and was originally included in domain 1 of the WHOQOL-AGE, was loaded in domain 2 (‘satisfaction with economic and social well-being’) for the rural sample and domain 1 (‘satisfaction with physical and mental health and well-being’) for the urban sample. Obviously, this item was comprehended in different ways by rural and urban older adults, but it loaded consistently in domain 2 in the overall dataset. Similarly, item 11, which relates to satisfaction with opportunities to continue achieving in life, was loaded in domain 1 for the rural sample, in domain 2 for the urban dataset, and shared with both domains in the overall dataset. Nevertheless, since its loading is higher for domain 2 and it is conceptually closer to ‘satisfaction with economic and social well-being’, item 11 was assigned to domain 2 of the Turkish version.

According to the original scale structure, items 2–8 formed domain 1, items 9–13 formed domain 2, and item 1 was shared by both domains. Based on this original structure, the goodness-of-fit statistics of the WHOQOL-AGE-TR generated by CFA were CFI=0.89, Tucker Levis index (TLI) = 0.87, RMSEA=0.12, and $\chi^2/df = 8.26$. In comparison, the goodness-of-fit statistics of the newly proposed WHOQOL-AGE scale structure based on the EFA
were CFI=0.83, TLI=0.81, RMSEA=0.073, and $\chi^2$/df=8.26.

Convergent validity results are presented in Table 4. The Katz ADL index physical dependency categories were sensitive to the domain scores of both the original scale structure and the proposed alternative scale structure (P<0.001). On the other hand, the difference between the correlation coefficients of the Katz ADL index score and the two domain scores of the proposed alternative structure (0.58 vs. 0.41) was greater than with the original scale structure (0.51 vs 0.47), indicating there is better convergence between the domains of the alternative scale structure proposed in this paper.

The criterion validity of the WHOQOL-AGE-TR was tested by regressions of the general QoL item (item 1) against the individual items of WHOQOL-AGE (table 5). The R2 values for both domains are acceptable. Except items 6 and 10, all the other items have a meaningful relationship with reference item 1. All of the Variance Inflating Factor (VIF) values are in acceptable limits rejecting any co-linear relationships between items.

**DISCUSSION**

WHOQOL-AGE has just recently developed as a hybrid instrument of two QoL scales: EUROHIS-QOL 8 (15) and one of the three short versions of the WHOQOL-OLD (16,17). Both of the mother tools (i.e. WHOQOL-BREF and WHOQOL-OLD) consist of four and six domains, respectively. Although the invariance of the WHOQOL-AGE among three different populations was presented (18), there is a need to examine the scale structure of the WHOQOL-AGE for different cultures and populations. Thus, this research tested the goodness of fit of the Turkish WHOQOL-AGE-TR against the original structure using exploratory and confirmatory approaches. The main reason for using the exploratory approach is the different scale structures of the EUROHIS-QOL 8 between the Turkish validation study (4) and some other country-specific data (Romania, Slovakia, and Israel) in a global EUROHIS study (15). In the Turkish validation study and especially in the Romanian sample of the global EUROHIS study, the EUROHIS-QOL 8 revealed a two-domain structure. Additionally, the developers of the WHOQOL-AGE proposed two different item compositions for the scale. Caballero et al. (8) suggested that item 1 be a shared item between the two domains.

**Table 4.** Convergent validity of both the original scale structure and alternative scale structure by using daily living activities assessed by KATZ index.

| Developer’s (Original) scale structure | Independent (n=390) (a) | Partially dependent (n=141) (b) | Totally dependent (n=19) (c) | P** (post hoc*** | KATZ index score (Spearman’s Rho)
|---|---|---|---|---|---
| Domain 1 | 69.77± | 56.32± | 43.32± | <0.001
| Domain 2 | 66.742± | 54.13± | 44.36± | <0.001
| Our alternative scale structure* | Domain 1 | 68.03± | 51.04± | 36.28± | <0.001
| Domain 2 | 68.41± | 58.16± | 48.90± | <0.001

* Domain 1: Satisfaction with physical and mental health and well-being; Domain 2: Satisfaction with economical and social well-being; **Kruskall Wallis ANOVA ***Mann Whitney U (pairwise comparisons, type 1 error was considered as <0.015)
whereas Santos et al. (18) classified item 1 only in domain 1 of the WHOQOL-AGE.

The distribution parameters did not indicate any problems for any of the items. Skewness and kurtosis are in acceptable limits for all items of the WHOQOL-AGE. The mean WHOQOL-AGE score of this study sample was around 64 whereas the results of a COURAGE study presented by Raggi et al. (19) gave overall higher mean WHOQOL-AGE scores (Finnish 78, Polish 70, and Spanish 74). These score differences can easily be attributable to the mean age of the study samples. The mean age of this study sample was 73 while that of the COURAGE study had a much younger mean age range of 45–57.

Reliability analyses of the original scale structure were also found to be within acceptable limits and consistent with the original development papers (8,18). The Cronbach’s alpha values for both domains were above 0.70, and the ‘if item deleted’ alpha values indicated that all items positively contributed to their domains. In terms of item success, all items except item 9 had significantly higher correlation coefficients with the domain they belonged to than with the other domains. Item success was about 92% (12/13), confirming the adequacy of the internal consistency.

The known groups validity analyses revealed satisfactory results for the original scale structure. As expected, the existence of any chronic illness, physical dependency, or physical/psychological abuse revealed quite high ES values. The

*q1 (general quality of life item) as dependent variable; **VIF: Variance Inflating factor as an indicator of colinearity.
discriminating effects of level of education, health, physical/psychological well-being, social support, abuse, and dependency were all confirmed by the previous QoL literature on the elderly (14,20,21, 22).

The EFA was run by principal components analyses using an oblique (direct oblimin) rotation since the correlation coefficient between the two suggested domains of the WHOQOL-AGE was 0.82, which a number of statisticians have suggested is a high correlation. Due to the same rationale (i.e. correlated domains), the WHOQOL-AGE developers also used a geomin rotation, which is designed as an oblique rotation (23,24). Hence, direct oblimin rotation stabilized the item loadings of the varimax rotation, allowing for the proposal of an alternative scale structure. The two-domain solution of the WHOQOL-AGE-TR explained 62.5% of the variance, which is very close to the 65.0% of the development study (8).

Based on the EFA of the Turkish data, the CFA results are somewhat contradictory between the original scale structure and the proposed alternative scale structure, so the goodness-of-fit statistics that were generated for both the original and the proposed scale structures need to be reviewed. As conventionally suggested, three goodness-of-fit indices (CFI, TLI, RMSEA) and a badness-of-fit measure (chi-square) were used in this study. Beginning with chi-square, as the original research did (8), this study also could not reach an acceptable $\chi^2/df$ figure (<2.0) since this measure is sensitive to sample size. We found similar CFI and TLI figures, both less than 0.90, for the original scale structure (8,18,19,25) and the proposed alternative scale structure. However, the RMSEA values are quite different between these two scale structures. The RMSEA value was 0.12 for the original scale structure whereas it was 0.073 for the alternative scale structure. The CFI statistic assumes that all latent variables are uncorrelated, but the latent variables are correlated in this study. Therefore, the RMSEA is more reliable than the CFI for this study, which means that the alternative scale structure may be better than the original scale structure from the COURAGE study.

The Katz ADL index was used to test the convergent validity of the WHOQOL-AGE based on the hypothesis that high physical dependency (as assessed by the KATZ ADL index) is expected to correlate with physical wellness items or domains. The results showed that the difference between the correlation coefficients of Katz ADL index and the domain 1 and domain 2 scores are greater for the alternative scale structure (0.58 – 0.41 = 0.17) than the original structure (0.51 – 0.47 = 0.04) (Table 6). The fact that domain 1 of the alternative structure is composed of more concrete health and well-being items may explain the higher correlation coefficient between the Katz ADL index score and domain 1 (‘satisfaction with physical and mental health and well-being’) score and the lower correlation coefficient between the Katz ADL index score and domain 2 (‘satisfaction with economic and social well-being’) score of the alternative scale structure. This indicates a good convergence and divergence of the alternative structure of the WHOQOL-AGE-TR.

**CONCLUSION**

The new alternative scale structure proposed in this paper is moderately compatible with the original scale structure of the WHOQOL-AGE proposed by the developers of the instrument. An alternative two-domain scale structure is suggested in this paper with a better RMSEA value than the original structure. The two domains of WHOQOL-AGE generated in this study are called ‘satisfaction with physical and mental health and well-being’ and ‘satisfaction with economic and social well-being’. Further studies are needed to test the original and alternative scale structures of the WHOQOL-AGE in different populations and cultures.
